ABSTRACT

Recent progress in the steer-by-wire technology has taken a significant improvement in vehicle safety and driving performance. By completely disconnecting the steering wheel from the tires provides excellent flexible features for vehicle dynamic control, it also introduces some practical difficulties for steering system control. The purpose is increase the system flexibility regarding vehicle dynamic control and safety and decrease design and production costs for the manufacturer. In this project, a novel method is being proposed for steer-by-wire technology to be used in road vehicles. This method discards the use of any mechanical linkage between the steering wheel and the road wheel’s steering mechanism. This is achieved by using angular absolute position sensor to detect the position of the steering wheel. A Brushless DC Motor employed to emulate the steering feel force feedback from the tire on the steering wheel. Pneumatic actuators control the road wheels to control the steering angle.

Therefore, the main objectives are as follows:

- Steer by Wire (SbW): Removing any mechanical linkage between the steering wheel and the road wheels.
- Steering wheel position determination and translate to the road wheel controller.
- Creating the desired force feedback onto steering wheel

The level of achievement to the objectives was found completely satisfactory. The position measurement and conversation was precise according to experimental results.
The torque controller has made reasonable force feedback on the steering wheel, and it provided same force output due to the constant input in experiment repetitions.

ÖZ

Dolayısı ile projenin amaçları şöyledir;

- Kablo kumandlı direksiyon sistemini, konvansiyonel mekanik bağlantıları kaldıracak oluşturmak
- Dümen açısını tespit edilmesi ve tekerleklerle aktarılması
- Tekerleklerde oluşan kuvvetin sürücüye geri dönüşüm olarak aktarılması

Projenin amaçları başarılı bir şekilde uygulanmıştır. Dümenin pozisyon ölçümü ve çevrimi elde edilen deney sonuçlarına göre kesinliği yüksek olmuştur. Tork kontrolü yine elde edilen deney sonuçlarına göre doğruluğu ve kesinliği yeterli bulunmuştur.
Anahtar Kelimeler: Kablo kumandalı direksiyon sistemi, pnömatik, InstaSpin, Tork Kontrolü
DEDICATION

To My Family.
ACKNOWLEDGMENT

I would like to record my gratitude to Asst. Prof. Dr. Davut Solyali for his supervision, advice, and guidance from the very early stage of this thesis as well as giving me extraordinary experiences throughout the work. Above all and the most needed, he provided me constant encouragement and support in various ways. His ideas, experiences, and passions have actually inspired and enrich my growth as a student. I am indebted to him more than he knows.

I would like to acknowledge the members of my graduate committee for their advice and guidance, most especially Prof. Dr. Hasan Demirel for all his advice and encouragements.

Special thanks for Mrs. Samira Asgari for her support and motivation on finishing this project and who has been a good friend to me. I am grateful in every possible way.

My thanks go to my friends who helped and encouraged me during the period of my studies and this thesis such as Mrs. GhazaalSheikhi and Mr. Payam Zar Bakhsh for his crucial contribution to this study.

Finally, I want to thank my parents for their patient support throughout all my years in school and who would have been just as happy had I decided to do something else.

Chapter 1

INTRODUCTION

Drive by wire technology is being increasingly used by many automotive manufacturers for vehicle products. The Drive-by-wire (DbW), replaces the conventional mechanical linkages and mechanical actuators like steering column, pumps, intermediate shafts, pumps, belts, coolers, vacuum servos and master cylinders with electronic control systems and electromechanical actuators in the vehicle. In DbW technology, the goal is to achieve a flexible control system. The DbW gives this ability to electronic control systems and electronic decision makers to take over the vehicle control to give a comfortable driving experience to the driver and also increasing the safety in case of emergency or loose of control by the human driver.

One of the most challenging topics in the Drive-by-wire’s subsystems is a steer by wire control system. The Steer by wire system eliminates the mechanical linkage between the steering wheel and road wheels. In a conventional car, there are some mechanical linkages and hydraulic or electric steering assist which are replaced with the combination of electronic control systems and electromechanical actuators to act as vehicle steering system. Figure 1, illustrates a conventional direct steering system based on rack and pinion mechanical linkages.
In the Steer-by-wire system (SbW), an electronic control system controls the vehicle’s steering angle by getting the position of the steering wheel. An electromechanical actuator helps the Steering Electronic Control Unit (SECU) to adjust the tires angle in the proper position. The conventional mechanical linkage between the road wheels and the steering wheel gives a road condition feeling to the driver through the steering wheel. However, in the SbW system all the mechanical connections are removed, so to give real driving experiences to the human driver, the electronic control system should be able to create conventional vehicles steering feel on the steering wheel by using electromechanical actuators.
Figure 2 illustrates the SbW general schematic. The steering wheel actuator emulates the steering feel on the steering wheel and also measures the Hand wheel position and send to the electronic control unit. The electronic control unit is in charge to get the measured lateral forces on the tire and use it in the steering wheel actuator control. Moreover, the electronic control unit gets the Hand wheel position and controls the road wheel steering angle accordingly.

Therefore, the main objectives are as follows:

- **Steer by Wire (SbW):** Removing any mechanical linkage between the steering wheel and the road wheels.
- **Steering wheel position determination and translate to the road wheel controller.**
- **Creating the desired force feedback onto steering wheel**

In the second chapter the literature review and the other studies are discussed and in continue the third chapter is about implementation methodology and all used
hardware and actuators are introduced. Finally, the fourth and chapter represents the results for the experiments. In the last chapter the conclusion and future works are represented.
Chapter 2

LITERATURE REVIEW

This chapter is intended to provide information about single design methodologies for the Steer-by-Wire (SbW) systems. Steer by Wire uses a servo motor to control the angle of the front road tires by getting the commands from steering wheel from the driver, and also fed back road forces and conditions on the front tires to the driver through an actuator which is connected to the steering wheel.

2.1 The single design method for the SbW

Asai and et al. [1] proposed an updated single servo drive method of SbW implementation. SbW system structure which is used in their research and many other types of research in this field, illustrated in Figure 3. Steering wheel mounted on geared Brush DC motor with motor angle sensor installed on it. The connection between the steering wheel and DC Motor has been established with torque sensor which measures the applied torque on the steering wheel by the driver. Brushless DC motor connected to the steering rack in order to make desired force on tires to change tires angle. A current sensor measures Brushless DC Motor current for calculating the motor force. A motor angle sensor is used to coordinate rack position which is used in position feedback. Signals from the current sensor and the angle sensor are collected by the motor driver and send to the ECU. Likewise, the torque and the current sensor signals from steering wheel collects by steering wheel’s motor driver and send to ECU as the same way. [1]
The proposed method of Asai et al. [1] to control SbW system is shown in Figure 4. The Control block can be divided into three main part. Namely, steering wheel actuator unit, Road wheel actuator subsystem and Road Condition force estimator part. The main reason to use steering wheel actuator is to apply force on the steering wheel that reflects road conditions on it. In Asai’s implemented the system, steering wheel is connected to a brushless DC (BLDC) motor shaft and another side of the motor shaft has an angle sensor to obtain steering wheel position. A current Proportional Integral controller, controls the BLDC motor torque, with Torque Command signal as a reference signal and the motor current from a current sensor as a control loop feedback signal. The Torque Command reference is summation of the Torque reference signal and torque compensation signal. The torque reference signal is obtained from reaction torque map which maps external torques on the front tires.
to steering feel force feedback. The Compensation Unit gets the angle, current and reaction torque as feedbacks from the steering wheel and generate feedback compensation signal which is used to stabilize the system and generate better feeling on the steering wheel. The angle sensor on the steering actuator is also used to get steering wheel angle as a set point for road tires position controller.

The road wheel actuator as it is proposed in Asai et al. controlled by a Proportional Derivative position controller and a PI current controller respectively. The position controller uses steering wheel angle sensor as a reference and use rack position sensor as position feedback to follow steering commands properly. The current controller is used to limit torque in desired value.

A disturbance observer is employed to observe both current and position of the road actuator to estimate desired force which should be applied on the steering wheel. Its output fed back to steering torque controller after passing through gear ratio converter and reaction torque mapping block.

In conclusion the proposed method in Asai and et al. [1], is using two motors, one for controlling road tires and the other to control the steering wheel. Using disturbance observer in this research has an adequate response to steering feel desired forces on the steering wheel, according to their experimental results in their research.
2.2 Force feedback and Steering feel

One of the challenging issue in the procedure of replacing the conventional mechanical steering wheel with the SBW; is finding a method to emulate the force feedback from the road tires to the steering wheel.

There are different force feedback methodologies in the literature. There are a direct method, Mathematical method, and Hybrid fusion method.

2.2.1 Direct methods

In Nguyen’s [2] proposed method, the steering feeling is recreated by measuring the electrical current in the motor that drives the front wheel using a simple current sensor. The innovative aspect of the work is using a simple sensor to measure the feedback force and improve the real driving feeling accordingly. For mapping related
torque, angle effect and velocity effect terms are considered in two equations for estimating the force feedback. The proposed scheme has been simulated using LABVIEW and compared with some conventional methods of steering feeling reproduction. Simulation results have proved the efficiency of the method compared to the approaches based on force measurement or disturbance estimation.

From the mechanical perspective, the feedback force is generated by friction, damping and the moment of inertia in the front wheel. Wheel rubber properties, the speed, and other unknown factors influence the force feedback as a wheel. In fact, the driving feeling is produced because of this total force. This feeling has two basic components namely the velocity effect component and the angel effect component. This concept is the main idea of the torque map approach in which the angle of the navigating wheel and the velocity of the vehicle are measured. These measurements are utilized to implement the real sense of driving [2].

Another proposed approach for producing steering feeling is the method proposed by Pastorino et al. [3] based on the amplifier-motor-gearbox model. In this study, the force feedback that needs to apply on the driver is evaluated by an assembly constitute of linear quadrant servo amplifier, a coreless permanent magnet DC motor, and double stage terrestrial gearbox. The model is created based on physically significant parameters that are precisely estimated by an accurate identification process. As all the parameters of the proposed model have a direct physical interpretation, model identification procedure has been implemented in a straightforward way. Model assessment is performed by means of three real world experiments. According to the valid data collected in three real driving conditions,
the model simulated in MATLAB Simulink accurately fits the dynamics of the
typical driving situations.

2.2.2 Model based mathematical methods

An innovative method has been proposed by Mehdizadeh [4], in which a reference
linear model of the vehicle is used as a virtual vehicle to reproduce the appropriate
steering feeling. In SbW vehicles that driver is assisted by a lane keeping system or a
steering assistant system, generating the realistic sense of driving is crucial. In fact,
in these systems the steering feeling should be reproduces artificially as a force
feedback at the steering wheel. However, this is not possible to apply this torque on
the front wheel as it disturbs the function of automatic lane keeper. Applying this
force on the wheel can simply mislead the controller since it is inferred as an
unnatural behavior; the phenomena that may put the system in an unstable state. In
[4], the results of simulations have confirmed that the proposed artificially generated
force feedback does not intercede with the lane-keeping controller.

Another approach to tackling the problem of steering feeling is based on real-time
fuzzy Proportional Integral Derivative (PID) controller that gives the driver a
realistic feeling at different vehicle velocities [5]. The proposed system is designed
and investigated in five stages. In the first and second step, the steering wheel and the
aligning torque are mathematically modeled. Then, the scheme of the road feeling
control is devised. The next step is the design of the fuzzy PID controller. Finally,
the proposed method is evaluated by simulated experiments.

Jie [5] also performed some simulations to evaluate the relation between the input
angle and the torque in an Steer By Wire (SbW) vehicle with a conventionally driven
one. The simulations are conducted in low speed and high speed for better comparison. Experimental results have shown that while in high speed the conventional vehicle is more efficient, at low speed, the Steer by Wire (SBW) vehicle is more accurate. In fact, in when the speed is low, input angle is smaller in SBW system compared to conventional vehicle. Also, according to the simulations, it was observed that the angle of entry and the torque required for steering were significantly smaller in SBW system than that in the conventional vehicle. Furthermore, investigations of the angle ratio have revealed that angle ration can be changed when the velocity is in the range of 20km/h to 100km/h. Simulation results have shown that the force torque could not be altered at high speeds larger than 100km/h as well.

2.2.3 Hybrid methods

Utilization of brushless motors for creating steering feeling has been proposed in a study by Bertacchini [6]. The force feedback system is a plain design based on a brushless motor as the force actuator. Evaluation of the suggested platform in Figure 5 is performed using ‘hardware-in-the-loop’ or briefly Hardware In the Loop (HIL) experimental settings. Firstly, the dynamics of SBW vehicle are modeled to be employed in virtual implementation. The model is also applicable to the validation procedure of the proposed force feedback reproduction method. It has stated in the paper that experimental results proved the efficiency of the control algorithm for SBW system. As a matter of fact, the electronic control unit (ECU) realization of the brushless technique has reproduced a natural steering feeling to the driver compatible to common driving feeling. Proposed system in Bertacchini et al. research illustrated in Figure 5. They used a well-known bicycle model [7] for virtual hardware of their experimental HIL model. This model is a simplified model of vehicle steering

In Bertacchini study, Results shows that using Field Oriented Control (FOC) method to control BLDC motor has an acceptable reproduction of conventional steering feeling.

![Figure 5: Bertacchini et al. Proposed HIL model [6]](image)

An approach using heading and lateral error correction is proposed by Switches [8]. His algorithm has a lane-keeping controller in the steering feeling reproduction system. The stability degree of the SBW system is measured in different situations where alternative sources are exploited to create the force feedback. In fact, the stability of the vehicle is crucial in all the strategies implementing a steering feeling procedure. While an SBW vehicle can be directed to an unstable state by a force...
feedback system (specifically when there is no driver input), a stable system does not guarantee a high-quality steering feeling. Investigation results of the study, have revealed that by keeping the steering feeling system in an acceptable condition, changes in the force feedback or the controller responsible for lane keeping, have a profound effect on the vehicle performance.

Balachandran et al. [9] in the starting proposed a simple model of steering feel to capture the effects of tire torques, power assist and modifications of natural inertia and steer by wire steering system dumping [9]. These parameters do not just depend on steering system model because the vehicle dynamic also affects them in reality. To tune this parameter to feeling desired torque on the steering wheel, using a simple vehicle dynamic is proposed in this research. In the conventional steering system three major parameters influences the steering feel which are represented as follows: a) torques due to inertia b) tire moments c) torque which is affected by power assist.

The simplified model is presented in Balachandran research [9], incorporates torques and tire moments according to steering system characteristics as well as simplifying
power assist model to be more general. Based on proposed model in this paper steering wheel motor torque is the sum of damping torque, and inertia torque and assisted tire moment for combined effect of the power assist, jacking torque and the alignment moment.

Moreover, according to Balachandran’s [9] study, to recreate real steering feel on steering wheel they used objective performance measure to evaluate on-center handling and are obtained by performance of weave test according to appropriate standards. Steering feel of the vehicle, during straight line nominal driving is called on center handling. The performance measures in this paper obtains data from following parameters: 1) On-center feel; 2) return ability; 3) steering sensitivity; 4) linearity; 5) effective torque stiffness. Finally, these measures are obtained using three cross plots: (a) driver steering torque input vs. hand wheel torque. (b) Hand wheel torque vs. lateral acceleration. (c) Lateral acceleration vs. steering torque inputs.

2.3 Steering wheel actuation and control

2.3.1 PID Control

PID (proportional-integral-derivative) controller is most commonly used control method in industrial control applications [10]. It is very simple, and it has very clear control principal. Furthermore, PID controller is very easy to implement regarding hardware and software implementation. A typical basic closed loop controller and its Inputs and outputs are illustrated in Figure 7.
Proportional control is used when the controller output signal is proportionally related to controller input error signal \( e(t) = r(t) - y_m(t) \). Representation for proportional control in time and Laplace domain are shown in Equ 1 [10].

\[
\begin{align*}
\text{Time domain} & \quad u_c(t) = k_p e(t) \\
\text{Laplace Domain} & \quad U_c(s) = K_p E(s)
\end{align*}
\]

Where the \( K_p \), represents proportional gain in given equations. Figure 8 illustrates proportion control block diagrams.

I-term is standing for Integral term in the PID controller, and it is used to compensate steady offset from constant reference input signal value. Also, Integral control eliminates proportional terms offset shortcoming, without the use of large control gain. The representation for time and Laplace domain of Integral controller are shown in Equ 2: [10]
Time domain  \[ u_c = k_i \int e(t)dt \]  \hspace{1cm} (2)  
Laplace domain  \[ U_c(s) = \frac{K_i}{s} E(S) \]

Where the $K_i$, represents Integral controller gain in given equations. Figure 9 illustrates block diagrams for time and Laplace domain. [10]

![Time domain - Laplace domain block diagram](image)

Figure 9: Integral control term [10]

Derivative controller brings prediction action into the controller by using the rate of change in the error signal as an input. This action uses the rate of change of an error signal and introduced by D term in a controller. Representation for time and Laplace domain for derivative control shown in Equ 2: [10]

Time Domain  \[ u_c(t) = k_D \frac{de}{dt} \]  \hspace{1cm} (3)  
Laplace Domain  \[ U_c(S) = [K_D S] E(S) \]

Where the $K_D$, represents derivative controller gain in given equations. Figure 10 illustrates the block diagram representation for derivative control [10].

![Time domain - Laplace domain block diagram](image)

Figure 10: Derivative control block [10]
In a real implementation, the use of derivative control needs more care than the use of proportional and integral control. For instance, due to noise amplification in feedback measurement, a modified derivative controller should be used instead of a pure derivative controller. However, derivative action has many useful features in real world implementation [10].

Various combination of introduced three term PID controllers are usually used in process controls to meet specific performance requirements. The combinations constructed with P, I and D controllers which are connected in series or parallel. The basic parallel PID controller formula is given as follow [17]:

$$U_c(s) = \left[ K_p + K_i \frac{1}{S} + K_ds \right] E(S) \quad (4)$$

Given formula is the basic formula for the parallel PID controller without any modifications that are necessary to make it work in real process control. For instance, the derivative form is used in pure form, and it is not usually implemented in this form due to noise amplification feature. Some modification should be applied on given parallel PID to make it implementable. The parallel PID controller is also known as decoupled PID form because it has three parallel paths. Figure 11 shows parallel architecture for PID controller. [10]
Early industrial PID controllers which are used in pneumatic or hydraulic actuators, had a series transfer function representation for PID controllers. However, modern PID controllers are implemented in digital and parallel, but this series formula is retained by some analog manufacturers to keep compatibility.

The very first technology of PID controller was analog. Primary PID controllers had simple dials marked by PID constants to tune the process control manually. There was a simple relation between the response to the plant and adjustment of PID parameters. In PID controller design procedure two-part should be considered in tuning: which terms should be used in PID structure and how to choose a numerical value for PID constants.

To choose the proper structure of a PID controller, understanding the effect of each term is necessary. The heuristic behavior of PID controller is captured in Table 1. The provided information is useful to understand each term of PID controller in transient and steady state.

### 2.3.2 Field oriented control

To achieve good performance, more complex control method should be used to control PM motors. With the power of mathematical processing which is offered by new embedded computers, we can use advanced control strategies, which can decouple the magnetization function and torque generation in Permanent Magnet motors. This decoupling of magnetization and torque is called rotor flux oriented control, or Field Oriented Control (FOC) [11].

According to the electromagnetic laws, produced torque in a machine is vector cross product of two magnetic fields [11]:

$$T_{em} = \vec{B}_{stator} + \vec{B}_{rotor} \tag{5}$$

This equation shows that when stator and rotor magnetic field are orthogonal, torque is maximum. To ensure a better dynamic and reduce torque ripple we should keep
rotor and stator magnetic field in 90° respectively. However, to keep this condition, we should know the exact position of the rotor.

The mission of the Field Oriented Control (FOC) is to vector control of stator current. This method based on a projection of three phase speed and time-dependent into d and q time invariant 2D coordinates. The torque (represented by q co-ordinate) and the flux (represented by d co-ordinates) are the necessary inputs of field oriented control machine [11].

![Diagram](image.png)

**Figure 13: (a, b, c) co-ordinates of stator current [11]**

Figure 13 illustrates stator current complex vector. This space vector should be transformed to two-time invariant coordinates. This action can be done in two steps:

1- Convert \((a, b, c) \Rightarrow (a, \beta)\) to make it two co-ordinate time variant

2- Convert \((a, \beta) \Rightarrow (d, q)\) to make it two co-ordinate time invariant
Figure 14 shows the stationary projection (the Clarke transformation) of (a, b, c) currents to two co-ordinate time-variant system.

By using Park transformation, two phase orthogonal system ($\alpha, \beta$) modified to d, q reference frame. Figure 15 shows the projection of time variant space vector to time invariant d, q.

Where, $\theta$ is the position of rotor flux. Following equation determines the flux and torque components [11]:

$$
\begin{align*}
    i_{sd} &= i_{sa} \cos \theta + i_{s\beta} \sin \theta \\
    i_{sq} &= -i_{sa} \sin \theta + i_{s\beta} \cos \theta
\end{align*}
$$

By using the right position of the flux, the d, q components become constant. Now both phase current converted to DC quantity. With constant $i_{sd}$ (flux) and $i_{sq}$ (Torque), torque control would be much easier [11].
Figure 15: d, q reference frame of stator current [11]

Figure 16 illustrates diagram for basic concept of FOC control. Two phase current measured and converted by Clark and park transformation method to d, q rotating reference frame. By comparing $i_{sd}$ and $i_{sq}$ with reference inputs control signal can be generated. With the advantage of this method controlling synchronous or PM machines is possible with just changing reference flux and determining rotor flux position.

Figure 16: Basic concept of FOC [11]
Chapter 3

METHODOLOGY

The aim of this study is to recreate steering feel and forces from the road wheels on the steering wheel in the steer by wire system (SbW). In this research, a new method of actuation for road tires is proposed. A pair of pneumatic actuators is used to control the tires angle, instead of using servo motors which are used in many studies before. Reproducing steering feel is achieved by getting force feedbacks from the pneumatic actuators and emulate measured force on the steering wheel by using BLDC motor. Three main parts of implementation methodology are as follows: Mechanical, Electrical, and Software.

Figure 17 illustrates an overview of proposed method in this study. Front road wheels are connected to chassis through control arms and a pneumatic cylinder, so Rod-ties replaced by the pneumatic cylinders to control the steering angle of tires. A pneumatic position controller controls the pneumatic cylinder’s shafts position to adjust tires angle. An air pressure sensor is used to measures the air pressure inside the pneumatic cylinders to measure forces on the road tires. Pneumatic cylinder equipped with a linear position sensor, to coordinate cylinder shaft position by using the pneumatic controller. Also, the measured position feedback to the steering wheel actuator to set it at the proper angle. The Hand wheel is connected to BLDC motor through a gear mechanism. The gear coupling is used to increase the BLDC torque on hand wheel and increase shaft turning range to achieve high precision.
controllability. The absolute position sensor is employed to measure steering wheel exact position which is used in the pneumatic controller position command. Main controller estimates desired force should be applied on the steering wheel to reproduce steering feel and send it to the BLDC driver. The BLDC controller unit controls the BLDC motor with desired torque according to the amount of force on the tire.

Figure 17: Pneumatic SbW System used in current study
3.2 Mechanical

The mechanical section introduces the mechanical actuation design and the reason behind the selected actuators. Figure 18 illustrates the mechanical design overview for implemented electric vehicle’s steering system.

![Electric Vehicle steering system mechanical design overview](image)

Figure 18: Electric Vehicle steering system mechanical design overview

A single seated Electric Vehicle (EV) is selected to implement the proposed pneumatic steer by wire system which the front tires and steering system are shown in Figure 18. The main parts to play steering wheel role are described in the illustration. The main parts of this implementation are Handwheel, Absolute Position Encoder, BLDC Motor and Pneumatic actuation unit (PAU).
3.2.1 Steering Wheel Actuation

After the methodology design, the very first step is the sizing calculations for actuators and also selecting the proper sensors to achieve good control performance. According to the Rosth study [12], the maximum desired force desired to turn the steering wheel is represented in Figure 19. According to the Rosth research, the maximum applied force on the steering wheel is when the vehicle is in the zero speed or the Parking state. The provided force graph in Figure 19 is for typical road vehicles. The maximum desired torque that should be applied to the steering wheel to reproduce the conventional cars steering feel be presented approximately 4 (Nm).

![Figure 19: Steering wheel desired force in power assisted steering system][13]

A gear mechanism transfers the BLDC motor’s force to the steering wheel. The gear ratio is from the Motor to the steering wheel is 1:5.2 (18:95) respectively. The gear mechanism increases the motor torque and decreases the speed to improve the motor’s controllability range at the zero speed and also increase the power. According to Forkenbrock and et el. [13] research in the US National Highway Traffic Safety Administration Organization, the maximum steering wheel speed rate in the highest maneuverability depends on the car type and also driver behaviors. The
test has been taken with a different car and four different drivers. The test
environment condition satisfies the ISO 3888-2 standard. The standard defines the
test condition for; Test track for a severe lane-change maneuver to avoid the
Obstacles. So the highest desired steering wheel maneuverability speed is tested in
Forkenbrock’s test report.

The test is taken with four different vehicles and four different drivers. Table 2 shows the results of tests on the test track with ISO 3888-2 standard and with disabled Electronic Stability Control system. The maximum steering wheel according to Table 2 is 963 degree per second. The 963 degree/second is equal to the 160 [rpm] for the steering wheel. Hence the steering wheel coupled to the motor by using the gear mechanism and the conversation ratio for the gear coupling is 1:5.2, so the maximum desired speed for the BLDC is 834[rpm]. The given formula [Equ 5] calculates the power for BLDC motor [17].

\[
\text{Motor Power (KW)} = \frac{(\text{Desiered Torque [N.m]} \times \text{Speed [rpm]})}{9.5488}
\]  

(5)

Where the maximum desired torque according to the Figure 19 is 4 Nm. The maximum desired speed of the BLDC motor according to Table 2 be calculated
834[rpm]. So the BLDC motor power should be more than 0.35 [KW] or 350W to satisfies the maximum maneuverability steering wheel speed. A 350W 3 phase BLDC motor is selected to drive the steering wheel. Figure 20 shows the BLDC motor, and the coupling to the steering wheel through the gear coupling mechanism.

![Figure 20: Connected BLDC motor through the Gear Mechanism](image)

The belt coupling mechanism connects the absolute position encoder to measure the accurate steering wheel position. Figure 20 illustrates The steering wheel position sensor and its connections to the steering wheel rod. Theory of operation of position sensor will be described in detail in the electrical section.

### 3.2.2 Road wheel actuation

In this research as it introduced at the beginning of this chapter, Pneumatic cylinders control the front tires steering angle. The pneumatic should be able to change the tires angle in the full load weight. There is not any fixed force for tires available because the forces on the front wheels are strongly dependent on car dynamics, weight and mass center. Especially, in the three wheel selected car for this research, forces on the tires are different from four-wheel vehicle. Figure 21 shows the
schematic for the pneumatic steering actuator and the connections between main items.

Figure 21: Front-wheel pneumatic steering system’s schematic

The very first step in cylinder sizing calculation is to find the force on the KINGPIN. The Tie rod converts the pneumatic cylinder’s linear force to the amount of necessary torque to change the tires angle which is connected to KINGPIN point. To calculate the required torque to change the tire angle a simplified formula is given as follows [12]:

$$ T = \frac{W u}{\sqrt{\frac{B^2}{8} + E^2}} $$  \hspace{1cm} (7)

Where \( T \) is kingpin torque in inch/lbs. \( W \) is vehicles weight on the front tires; \( u \) is friction coefficient. It can be assumed 0.7 [12] for most applications which are using normal car tires. \( E, B \), are tire size and distance from Kingpin which illustrated in Figure 22.
In the selected electric vehicle in this study, W is 84 Kg, B is 104 mm, E is 82.2 mm. So the required torque to change the tire steering angle on the Kingpin calculated 52 Nm. To convert a rotational force to the linear force the given formula is used as follow [12]:

$$F = \frac{\text{Torque}}{r \times \sin \theta}$$  \hspace{1cm} (8)

Where $F$ is required linear force should be generated by the pneumatic cylinder in Nm, $r$ is the connection arm length between the pneumatic rod and the Kingpin which is illustrated in Figure 23. Moreover, the $\theta$ is the angle between linkage arm and pneumatic actuator’s rod.
The required force from pneumatic actuator according to the given parameters in Figure 23 can be calculated by using Equ 8 as follows:

\[ F = \frac{52 \text{Nm}}{0.105 \sin (75)} = 508 \text{ [N]} \]  \hfill (9)

The last step in pneumatic cylinder calculation is to find the bore size of the cylinder which can be calculated with given formula [12]:

\[ d = \sqrt{\frac{4F}{\rho \pi}} \]  \hfill (10)

Where \( \rho \) is pneumatic air pressure in Pascal and \( F \) is desired Force from pneumatic cylinder and \( d \) is the pneumatic bore size in millimeter. The result for pneumatic cylinder bore size is 28.4 with safety factor 2. So the nearest standard value for the pneumatic cylinder is chosen by 25mm.
3.3 Electrical

Data acquisition and control system to implement ShW system in this study has three main blocks. Namely, steering wheel control block, road wheel actuator and sensors and central control unit to control all actuators.

3.3.1 Steering Wheel Position Sensors

In the steering wheel control part, there are two main actions should be considered, they are divided to control action and measurement actions. The control action is used to apply force on the hand wheel by using BLDC motor, and the measurement action is to measure hand wheel current position. An absolute position sensor measures the steering wheel shaft position which is used in road wheel position controller. BLDC driver controls motor torque by using measured motor current. Figure 24 illustrates an overview for hand wheel control.

![Figure 24: Steering wheel control diagram](image)

The absolute position sensors output is necessary to control the tires angle and also it is used to achieve best position control performance in the motor driver. To take angle measurement an industrial absolute rotary encoder from the Autonics is selected. The selected sensor in this research has the “EP50S8-1024-3-R-N-24” Part number, and it is shown in Figure 25.
The selected sensor has the resolution of 1024 steps per turn, and its data can be accessible through digital output with the gray coding standard. The reflected binary code, also known as gray code, is a digital numerical system where two sequential numbers are different with just one bit. The gray code is commonly used in error correction in the digital data transmission systems and industrial applications. The EP50S sensor is used reflected binary code to send position data out. So it has ten digital output line to be able to send out 1024 steps. Moreover, also it needs a power supply to power up digital input circuits. The absolute rotary encoders are using special kind of an optical disk to generate binary, BCD or gray outputs and also some absolute encoders use industrial serial data communication protocols to send out position data. The gray code generator optical encoder disk is shown in Figure 26.
In the current research, the road wheel position controller uses the position value from the absolute encoder as a position feedback to control the angle of tires. However, the position sensor’s output should be translated to controller compatible inputs. As it will describe in this chapter, the pneumatic controller needs 0 to 10V for linear actuator control. Hence the output from the position sensor is not compatible with controller’s acceptable input so it should be translated from digital gray code to analog zero to 5 volt for the pneumatic position controller to the 0-10V range. The position sensor’s data conversation block diagram is illustrated in Figure 27.

![Diagram of position sensor data converter](image)

**Figure 27: Position sensor data converter diagram**

An Arduino board is used to implement illustrated block diagram in Figure 27. The 74HC14 Integrated Circuit (IC) is used as a buffer to convert encoder output signal to TTL level for the microcontroller. The gray code to binary converter and mapping function blocks are implemented in microcontroller code which will be described in detail in software part. Digital to analog blocks are implemented by using Pulse Width Modulation output from Arduino board and passes through an analog filter to converted to DC value. The DC analog value is amplified and buffered by LM358 Operational Amplifier (OP-AMP) IC to the proper signal level. The PWM to DC signal filter and analog buffer is shown in Figure 28.
The cut-off frequency for illustrated analog filter in Figure 28 is 36.6Hz as it is shown in frequency response analysis in Figure 29. So this filter is ideal to filter the PWM signal and convert to suitable DC signal which can be used as feedback and reference.

![FREQUENCY RESPONSE](image)

Figure 29: Frequency response analysis for Analog filter

### 3.3.2 Steering Wheel’s BLDC Motor Torque

To emulate the steering feel forces on the steering wheel, we need an actuator to play the steering column roll. In this study, chosen actuator is a Brushless DC (BLDC) motor which is connected to BLDC driver to control and drive the motor. The BLDC driver should be capable of controlling the amount of force on the Hand wheel. As it was discussed earlier in this chapter, a bicycle HUB motor is selected as the steering
wheel actuator. This HUB motor can deliver up to 350W power to the shaft with 36V nominal working voltage.

According to the HUB motor specifications, the BLDC driver should be able to supply up to 10A and work with 36Volt. The FOC method is selected to drive BLDC motor and make sure that the motor is working with maximum adjusted torque. The FOC algorithm and torque control working with motor current, so accurate current measurement necessary in motor controller side.

![Image](image_url)

Figure 30: DRV8312-69M-KIT[11]

In this research to control BLDC motor and firmware development, the DRV8312-69M-KIT development kit chosen and it illustrated in Figure 30. The development kit equipped with TMS320F28069M Digital signal controller (DSC) from Texas Instruments (TI). The 28069M is one of TI’s motor control solutions which is optimized for motor control applications to achieve better performance regarding measurement and control calculations. Power drive unit in the DRV8312-69M-KIT development board based on DRV8312 3-phase BLDC motor drive solution from TI.
Figure 31 illustrates the general hardware overview for the BLDC driver. The three-phase BLDC motor needs three half-bridge driver to source and sinks current from motor stators. The DRV8312 has a three built-in half-bridge controller. Current shunt resistors are necessary on each leg’s ground side to convert the motor current to a voltage that measurable by the MCU’s Analog to Digital converter (ADC). FOC and torque control algorithms are using measured currents from motor phases. The DRV8312 has three PWM signal input to control high side switches independently, and also, it has three reset inputs to control low side switches as well. All measured currents by using external current shunts are feedback to the microcontroller to be used in FOC and Torque control process.

Main Micro Controller Unit (MCU) provides six complementary PWM outputs to control half-bridge drivers. The PWM units inside the microcontroller generate high-frequency PWM signals with desired dead time. Two inputs are considered to get pulses from incremental rotary encoders to measure speed and shaft movements. Moreover, 16 Analog inputs are available to measure the analog signal in the range of zero to three volts.
Eight channel of sixteen analog inputs are allocated to measure motor voltages and currents, and the remaining channels are wired out for adding other functions by users. In this research, an analog input is used to get data from Handwheel position sensor. According to the BLDC motor’s theory of operation is described in the second chapter, the six-step of a BLDC motor control procedure is shown in Figure 32.
In sensorless designs, the controllers are using back electromotive force (Back EMF) signal to estimate the rotor position to select the correct stator coil to switch it on or off.
off. Figure 32 shows, two different power level is applied to the stator coils. All currents and the back EMF’s for each phase illustrated respectively. Figure 32 demonstrates that the PWM signals control the high side switches, and the low side switches are just working in on or off states. Three resistor voltage divider measure the voltages on each line of motor inputs to extract the Back EMF signals for each phase. Figure 33 illustrates the voltage divider in the current design. A 47nF capacitor filters the input signals to reduce switching noises and improve the ADC measurement by increasing sample and hold unit performance.

![Back EMF Voltage divider](image)

**Figure 33:** Back EMF Voltage divider [11]

Power MOSFETs inside the DRV8312 amplifies the current and voltage to drive BLDC motor. In another word, the half bridge configured power MOSFETs, translate the MCU 3.3V output voltage to nominal motor voltage and also amplifies the deliverable current. Figure 34 shows the connection between the microcontroller unit and the power MOSFETs inside the DRV8312.
The FOC algorithm needs at least two phase current for the Park and the Clark calculations. In the current design, each half bridge’s current passes through the shunt resistors which connects each half bridge to the ground. Three ground lines which are illustrated by GND_A, GND_B, and GND_C, wired out from the IC to tie to the ground line through the shunt resistors.

The shunt resistors usually have low resistance and high power to measuring the passing currents to or from the consumers. Shunt resistor’s values are tiny; their typical value is between one to some hundred milliohms. The availability, low cost, good frequency response, and wide bandwidth are the advantages of using shunt resistors in designs. In another hand, ground shifting in case of using shunt on the ground lines, and high voltage common mode in case of using a positive voltage, non-isolated, power losses, and low voltage measurement noises are the disadvantage of using shunt resistors in current measurement. A small value of resistors helps to improve the drawbacks especially ground shifting, but the measurable voltage is decreased in return. Also, measurement noises increased due to amplification in the
measured shunt voltage. So there is a trade-off between power losses and the voltage drop across the shunt resistor. Measurement improves by designing good filter and using low noise amplifiers.

![Shunt voltage measurement amplifier](image)

**Figure 35:** Shunt voltage measurement amplifier [11]

The differential amplifier to measures the shunt voltages is illustrated in Figure 35. The amplifier unit shifts the input signal and also amplifies the input signal to increase the measurement resolution. The shift value is to measure the current in both sink and source way. When the load uses the current, the voltage value of the shunt resistor is positive with respect to ground and in vice versa, if the load passes the current through itself, the current shunt’s voltage become a negative value. The microcontrollers can only measure positive voltage. In the current design, input signal sum up with 2.5V to shift whole measured signal range into the microcontroller acceptable range. Finally, the output from amplifiers goes into ADC to convert to a digital value and used in FOC algorithm and torque control feedback.

All digital and analog parts need a power supply to power up. Hence, the difference voltage levels are necessary for each part, different power supply unit with different output voltages considered in this design. The very first voltage converter decreases
the 15-50V input voltage to 12V. This DC to DC level converter is configured in the buck switching topology with the use of TPS54160 switching controller and embedded power switch. The 12V voltage employed in DRV8312’s gate drivers for integrated MOSFETs. Figure 36 illustrates the DCDC voltage converter with TPS54160 controller from TI.

![Figure 36: DC to DC converter (11)](image)

Two linear voltage regulators considered to converts the DCDC 12V output voltage to 5V and 3.3V. The outputs from Linear Regulators supplies the analog amplifiers and control units.

![Figure 37: Linear regulators to make 3.3V and 5V (11)](image)

In the industrial applications, the safety and noise immunity are very crucial. In many designs in industrial and automotive fields, the inputs and outputs are isolated by
using opt isolators, galvanic isolations or transformers. The isolation helps to protect from incoming and outgoing high voltage surges and also to prevent the system from electromagnetic noises. In the BLDC motor driver, the serial communication interface is isolated by proper isolator ICs. The isolator ICs needs a power supply on both sides of isolation, so an isolated voltage should be produced on board, to power up the isolated side of the isolator IC.

![Figure 38: Isolated voltage converter [11]](image)

The DCH010505S is an isolated DC to DC converter to converts the input 5V voltage to separate 5V Voltage at the output. Moreover, a linear regulator converts the 5V to 3.3V to supplies the serial interface ICs. Figure 38, shows the isolated DC to DC converter’s schematic.

In the current design, A Controlled Area Network BUS (CANBUS) used to send and receive the commands to the BLDC motor driver. The CAN Bus is one of the most noise free and reliable communication methods in industrial and automotive environments. The physical communication layer based on differential signal transmits, like RS-485 and other differential serial protocols. Moreover, the software layer has CRC error check to control the incoming packets. CAN Bus communication will be described in detail in software part of this chapter. The
isolated digital to differential data converter for CAN bus is sends out or receives the commands by using ISO1050 IC.

![Figure 39: Isolated data communication interface [11]](image)

The CAN bus communication needs a 120-ohm resistor at the both end of the BUS to terminate signals and prevent the bus from reflecting back the signal to BUS.

### 3.3.3 Road wheels linear position sensor

As introduced at the very beginning of this chapter, a new steering wheel actuation method proposed in this research. In the proposed method in this study, the pneumatic linear actuator takes the control of tire angle adjustment instead of using electrical servo motors. A position controller controls the linear pneumatic cylinder’s shaft position by using mounted position sensor on the cylinder as position feedback. The reference signal to adjusts the rod position set by a main control unit that calculates the amount of shaft’s linear movement according to the steering wheel position. The selected position controller is an S2 pneumatic controller from the Enfield company. The S2 controller included a closed loop position controller by using linear position sensor to determine the actuator’s shaft position and control it with PID controller. The user interface software for the S2 controller gives access to the PID controller parameter and coefficients to adjust them according to the
application’s environment. The pneumatic position controllers are using pneumatic
servo valves to control the amount of pressure on the cylinder’s both end to set the
shaft in a proper position.

There are many kinds of linear position sensors available. Namely, Resistive
potentiometers, Linear variable differential transformers (LVDT), Magnetostrictive,
Optical encoders and Magnetic encoders. The resistive models have a fair accuracy
and price, and LVDT models have an excellent precision, but their prices are quite
high. The most widely used linear position sensors in the industries are the resistive
and LVDT models. In the current study, LVDT model selected to achieve accurate
position control and high precision data analysis and results. The LVDT sensor’s
theory of operation based on Transformers action. There are primary and secondary
coils inside the sensor. The position measured by moving the core between primary
and secondary coils where this moving changes the magnetic couple on the
secondary coil. Figure 40 Illustrates the electrical schematic for an LVDT position
sensor.

Figure 40: Electrical schematic for LVDT [14]
Figure 41, demonstrates the LVDT position sensor’s windings, core and electronic signal conditioning module.

![LVDT Linear Position Sensor](image)

**Figure 41: An LVDT Linear Position Sensor [14]**

The position sensor needs 12 to 24Volt power supply to power up the electric units, and position feedback output in the selected version is 0 to 10V voltage output which is compatible with industrial controllers like Enfield S2.

### 3.3.4 Road wheels Pressure sensor

The general method to measures the forces on the tire and steering rack is the road wheel servo actuator current measurement but hence in this study instead of using servo motors the pneumatic cylinder selected to controls the tires angle, so the current measurement method is not available this method. The proposed method using cylinder pressure measurement to determines the forces on the road wheel. The main control unit measures the amount of pressure inside the cylinder and estimates the proper force should be applied to the steering wheel. Figure 42 illustrates the selected sensor in this research. The PSE510-T01 works with 12-24V power supply and represents the measured pressure value in the range of zero to five volts.
3.3.5 Road wheels actuator controller

The selected pneumatic controller from Enfield is one of the most well engineered high accurate position controllers in the market. The S2 controller uses the servo valves to control the amount of pressure inside the cylinder. The Linear position sensor provides the shaft’s current position feedback and according to the provided feedback the controller adjusts the pressure inside the cylinder to get the shaft in the proper position. The S2 has a robust controller to control the position and also keep the position fixed due to external forces which applied to the shaft. An adaptive robust PID controller controls the rod position. A user interface software comes with a controller to adjust all PID parameters and also to set the environment control limitation such as position limits. The USB port connects the S2 controller to user interface software, USB port located on the driver. The driver works with 12 to 24 volts and accepts the commands in the zero to ten volts range. The position sponsor’s analog data comes to controller directly. Figure 43 shows the S2 controller from Enfield.
The S2 controller has an input for main high-pressure air and two output which should be connected to pneumatic cylinder both sides, and there is two exhaust output on the controller. Each tire has a set of position controller, a position sensor, and a pneumatic cylinder.

3.4 Software

A TMS320F28069M Digital Signal Controller (DSC) from the Texas Instruments controls the steering wheel BLDC motor and reads the steering wheel angle position from the Absolute Rotary Encoder. The DSC collects feedback signals from the angle position sensor, the current sensor, the motor voltage sensors, the input voltage and the road wheel position sensors and uses all gathered signals as input for control algorithms. Three PI controllers are controlling the steering wheel state. Each controller and the purpose of using that will be described in Control strategy part.

3.4.1 Torque Control Strategy

The force on the tires and the road wheel current position, are two main parameters that should be feedback to the driver to emulate the real steering feel on the steering wheel. The steering wheel control scheme is shown in Figure 44.
A series Proportional-Integral (PI) controller, which is implemented in the DSC firmware to control the forces is shown in Figure 45.

According to the Figure 45, the $K_i$ and $K_p$ for the given series controller can be calculated from parallel PID form as follow:

$$K_{p\text{series}} = K_p$$

$$K_{i\text{series}} = \frac{K_i}{K_p}$$
Where $K_i$ and $K_p$ are the parameters from parallel PID controller. In the series PI controller form, the gain for ALL frequencies is set by $K_p^{\text{series}}$, and the $K_i^{\text{series}}$ defines the inflection point (zero) in the series controller in rad/sec.

Texas Instruments Co. provides an InstaSPIN motor control library for the TMS320F28069M microcontrollers which has lots of control functions for FOC, FAST and PID control for BLDC motors. The main block diagram for the InstaSPIN library is shown in Figure 46.

![Figure 46: InstaSPIN controller block diagram](image)

There are two current controllers to controls the $i_d$ and $i_q$ which are introduced in the FOC chapter of this thesis. The Park, Clarke and the SVM conversation modules for the FOC implemented inside the microcontroller hardware to increase the speed and efficiency. The FAST (Flux, Angle, Speed, and Torque) estimation block, estimates
four fundamental parameters to control the motor speed and torque as well as providing the force and angle to use in position controlling.

The Fast algorithm estimates the motor’s four fundamental state by using the motor’s phase currents and phase voltages and also the main bus voltage as well as motor parameters like the inductance, resistance and motor type, and poles which should be set by the user.

In the current research, the FAST algorithm and FOC controller of the TMS320F28069M are employed to controls the amount of torque on the steering wheel. The desired torque amount on the steering wheel set by a pressure sensor on the pneumatic cylinder and the input from pressure sensor used as torque set point in the controller. The $i_q$ and $i_d$ define the torque limit on the BLDC motor’s shaft, so the torque set point defines the current limit value for the current controllers.

### 3.4.2 Position measurement and conversation

As it is illustrated in Figure 44, the absolute position sensor measures the Handwheel angular position. An Arduino board reads the absolute sensor and translates the digital sensor output to the road wheel controller voltage level. The angle sensor provides the 10-bit digital gray code for the Arduino board which should be first converted to the binary value to be meaningful for the digital to the analog unit.
Figure 47: Absolute position sensor to analog value procedure

As it discussed earlier in this chapter in the electrical section, the Pulse Width Modulated (PWM) signal passes through a low-pass filter to generate desired analog voltage for position controller.
Chapter 4

RESULTS

4.1 Experiment setup

The main objective in this study is to implement the new idea for the SbW system. The pneumatic actuator is employed to controls the road wheel angle instead of using servo motors. The pressure sensor on the pneumatic cylinder measures the lateral force on the tire and convert them to the analog voltage which is meaningful for the steering wheel BLDC torque controller. Moreover, the steering wheel position is measured by absolute position encoder and converted to the desired voltage for the pneumatic controller.

- Steer by Wire (SbW): Removing any mechanical linkage between the steering wheel and the road wheels.
- Steering wheel position determination and translate to the road wheel controller compatible input.
- Creating the desired force feedback onto steering wheel
Figure 48 shows the steering wheel sensor and actuator implementation and connections for this study. A steel rod connects the steering wheel directly to the position sensor. The gear coupling connects the BLDC motor’s shaft to the steel rod. The pneumatic actuator connects the tire kingpin to the vehicle chassis.
Figure 49 demonstrates the position sensor data convertor to the analog value for the pneumatic position controller. The signal high level for the position sensor is 24V, but the Arduino board can accept the signals on the digital input just high as 5V. So a resistor divider network reduces the voltage level in the accepted range by the Arduino.

The operational amplifier buffers the output voltage from low pass filter to prevent the signal from changes due to current sink from external sources.
Figure 50: BLDC Motor driver and experiment desk

Figure 50 demonstrates the experiment desk and the boards connection to the mechanical test bed.
4.2 Experiment methodology

4.2.1 Position measurement

Figure 51: Position validation setup

Figure 51 shows the test setup for position measurement validating and accuracy and error determination. An angle ruler measures the steering wheel absolute position to verifying the generated voltage from the Arduino board. The output voltage observed and recorded every 5 degrees as well as analog output voltage for the steering wheel full range. The whole range for the steering wheel starts from 40 degrees up to 140 degrees at the right end. The position and voltage recording repeated ten times for full range to achieve accurate results.
4.2.2 Torque Measurement

The torque measurement experiment done by turning the steering wheel for the entire steering range with the five different force applied on the steering wheel. The steering wheel moved at a constant speed of $5.2 \text{ rad/second}$ to make sure that required torque for the range remains constant during the Handwheel moving. Each experiment repeated for ten times for each force to rise the most reliable results.

Figure 52: BLDC Driver setup

Figure 52 shows the BLDC Motor Driver configuration and the current measurement sensors to determine the motor output current to calculates the BLDC output torque. The Code Composer Studio (CCS) shows all parameter for the controller board and all parameters can be recorded on the graph or as a table for the further processing.
Figure 53 demonstrates the test setup to measure the BLDC motor speed by using precision laser tachometer to make sure that the measured torque is at the constant speed.

4.3 Result analysis

The Hand wheel’s position and applying desired force on the Handwheel are two primary objectives in this research and implementation. As it discussed at the beginning of this chapter the position measurement had been done by moving in 5 degrees steps and measuring to output voltage to the position controller. Table 3 illustrates the measurements of the steering wheel position versus output voltages. The steering wheel initial position assumed at the middle. The full range for steering set by 50 degrees to each side. In Table 3 the first column shows the steering wheel position in 5 degrees steps. E1 to E10 stands for the first experiment round to 10th trial round respectively. Each round is started turning the steering wheel position from -50 degrees from the left up to the +50 degrees and record the voltage each 5 degrees. The given voltages in the table are in millivolt unit.

Table 4 represents the output torque on the steering wheel for five different limiting currents. Experiments repeated ten times to analyses the driver operation. Figure 55 and Figure 56 are showing the visual spread chart and 3D diagram for the provided information in Table 4.
Figure 55: Steering wheel Torque vs. Different current level spread chart

Figure 56: Steering wheel Torque(Nm) against Different current level (mA) diagram

4.3.1 Precision and Repeatability

The accuracy of a device is a degree of freedom from random output error for a particular input value. In another word, for a high precision device or a converter if a
large number of reading taken from the output for one particular input all should be very close together. The precision is not about the how output is accurate because the accuracy is how the reading value is close to the correct value but the precision is about the how the outputs are close together for and input in repeated experiments [14].

The publication of the ISO5725-1 standard describes the accuracy and precision. According to the ISO5725-1 specification, the Accuracy term is defined as the closeness of value to the real value and the general term Precision is the closeness of outputs in the sets of the results [15].

Statistically, the precision is defined as the standard deviation in statics calculation for a series of repetitive measurements [16]. The Standard Deviation $SD$, can be calculated with given formula as follow:

$$ SD = \sqrt{\frac{\sum_{i=0}^{N} (X_i - \bar{X})^2}{N - 1}} \quad \text{where} \quad \bar{X} = \frac{\sum_{i=0}^{N} X_i}{N} \tag{11} $$

The given formula for standard deviation calculates precision for the each position sample groups from Table 3. To calculate the total system accuracy, the Coefficient of variation is the normalized parameter which is a point to the variability of the data points. The normalized value derives from dividing the standard deviation by the mean value in each test and multiply it with100. The average of all normalized standard deviation (Coefficient variation) gives the whole system weighted precision.

<table>
<thead>

<tr>
<td>50</td>
</tr>
</tbody>
</table>

The weighted average for the entire system precision is equal to the sum of all normalized standard deviation divided by the number of experiments.

\[
Precision = \frac{\sum \text{Normalized SD}}{\text{Number of tests}} = \frac{0.042176}{21} = 0.0020
\]  \hspace{1cm} (12)

A coefficient variable of \%0.2 for precision shows that 68% of the outputs will be in the range of +/- 0.2% of the mean value and for the most of the time, the 95% of the outputs falls between +/- 0.4% of the average value.

Table 6 shows the standard deviation for the BLDC motor torque outputs for different experiments. The precision for the motor applied torque on the steering wheel can be calculated as follows:

\[
Precision = \frac{\sum Normalized \, S}{Number \, of \, tests} = \frac{0.295757}{5} = 0.0591
\]

(13)

A coefficient variable of %5.9 for precision shows that 68% of the torque outputs will be in the range of +/- 5.9% of the mean value and for the most of the time, the 95% of the outputs falls between +/- 11.8% of the average value.

4.3.2 Linearity

When the output from the system is linearly proportional to the input value, it is typically describing the system is linear. The standard procedure is to draw the best-fit line on the results graph. Figure 57 shows the results of the first experiment for entire steering range. According to the chart, the results are pretty linear, but some points are not on the appropriate line. Its also preferable to apply the least square line fitting formula. The maximum deviation of any of the output from the fitting line is defined as a non-linearity.
To find the best-fit line $y = bx + a$, over the given points by using the least square technique, the $a$ and $b$ constant should be optimized to minimize the error between the fitting line and the data points. Given below formulas calculates the value for $a$ and $b$ constants [14].

$$b = \frac{\sum(x_i y_i) - nx_m y_m}{\sum x_i^2 - nx_m^2} \quad \text{and} \quad a = y_m - bx_m \quad (14)$$

In the first step, the mean values of $x_m$ and $y_m$ are necessary. For the second step the $(x_i y_i)$ and $x_i^2$ for all x and y should calculated.

For the given data chart in Figure 57, the $x_m = 0$ and $y_m = 2019.381$ and $\sum(x_i y_i) = 442025$ and the $\sum x_i^2 = 19250$. With these value $a$ and $b$ calculates as follow:
\[ b = \frac{442025 - (21 \times 0 \times 2019.381)}{19250 - (21 \times 0^2)} = 22.96 \quad \text{and} \quad a \]

\[ = 2019.381 - (b \times 0) \quad (15) \]

By using the calculated values for \(a\) and \(b\) the best fit line can be written as follows:

\[ y = 22.96 \times + 2019.381 \quad (16) \]

Figure 58: Best-fitting line for 2nd Experiment

Figure 59: Best-fitting line for 3rd Experiment
Figure 60: Best-fitting line for 4th Experiment

Figure 61: Best-Fitting Line for 5th Experiment

Figure 62: Best-fitting line for 6th Experiment
Figure 63: Best-Fitting Line for 7th Experiment

Figure 64: Best-fitting line for 8th Experiment

Figure 65: Best-Fitting Line for 9th Experiment
According to Figure 58 to Figure 66, and the calculated line equation for each line and maximum deviation error provided in the figures, the linearity for all experiments is better than 99.98% for all tests in a position to voltage converter unit.

For torque measurement tests the line fitting equation applied same as the position line calculation.
Figure 68: Best-fitting line for 2nd torque Experiment

Figure 69: Best-fitting line for 3rd torque Experiment

Figure 70: Best-fitting line for 4th torque Experiment
Figure 71: Best-fitting line for 5th torque Experiment

Figure 72: Best-fitting line for 6th torque Experiment

Figure 73: Best-fitting line for 7th torque Experiment
Figure 74: Best-fitting line for 8th torque Experiment

Figure 75: Best-fitting line for 9th torque Experiment

Figure 76: Best-fitting line for 10th torque Experiment
According to Figure 67 to Figure 76 the maximum non-linearity is in the 6th experiment with 2.26% deviation from the best fit line. The average non-linearity in 10 experiment is less than 1.1% and the torque output’s linearity is better than 98.91% in average for all experiments. According to the provided graphs for linearity analysis, both position converter and torque controller have a good linearity response.

4.3.3 Range

The range is the maximum and minimum value of the designed system output. For the position converter, the angular input range is between -50 degrees to +50 degree from the steering wheel initial position (middle position). The voltage output minimum is 873 mV, and the maximum output voltage is 3170 mV for the specified range.

For the torque controller, the minimum input reference limiting current is 1000 mA, and the maximum limiting current is 5000mA. Moreover, the output limiting torque is between 1Nm up to 5Nm.

4.3.4 Error

There is some source of errors that disturbs the measurements and also cause the non-linearity and deviation in the results. Measuring instruments are playing the important role in data validation in this part. A digital oscilloscope is used to measuring the output voltage signal from the position converter module. The resolution for the oscilloscope is 1mV when the input is less than two volts and the resolution changes to 10mV when the input is greater than 2 volts. An angle ruler is used to observe the steering angle, the user reading angle and also the resolution of the angle ruler are the other source of the disturbance in the measurements. For the
torque controller, the current measurement circuit error can cause the deviation from the correct value.
Chapter 5

CONCLUSION

Drive by wire technology is being increasingly used by many automotive manufacturers for vehicle products. The Drive-by-wire (DbW), replaces the conventional mechanical linkages and mechanical actuators with electronic control systems and electromechanical actuators in the vehicle.

This is achieved by using angular absolute position sensor to detect the position of the steering wheel. A Brushless DC Motor employed to emulate the steering feel force feedback from the tire on the steering wheel. Pneumatic actuators control the road wheels to control the steering angle. Therefore, the main objectives are as follows:

- Steer by Wire (SbW): Removing any mechanical linkage between the steering wheel and the road wheels.
- Steering wheel position determination and translate to the road wheel controller compatible input.
- Creating the desired force feedback onto steering wheel

This study has shown that force feedback on the steering wheel by using the brushless DC motor has very precise and reasonable response to the steering feel emulation. Results are shown that, the precision of the torque controller in the full range movement of steering wheel spinning from has a coefficient variable of %5.9
as well as less 98.91% linearity or in another word less than 1.1% linearity error. The coefficient variable for precision shows that 68% of the torque outputs will be in the range of +/- 5.9% of the mean value and for the most of the time, the 95% of the outputs falls between +/- 11.8% of the average value.

The steering wheel’s position sensor voltage converter has a less than 0.02% non-linearity in average for all experiments. The coefficient variable for the implemented position voltage converter is 0.2%. A coefficient variable of 0.2% for precision shows that 68% of the outputs will be in the range of +/- 0.2% of the mean value and for the most of the time, the 95% of the outputs falls between +/- 0.4% of the average value.

In conclusion, the achieved results for all objectives have good precision and repeatability response as well as linearity for the entire range of working conditions. The provided experiment results in proof that the steering wheel force emulation and the position feedback from the steering wheel for road wheel tires are good enough to be replaced with the mechanical steering wheel.

The Motor driver uses the sensorless BLDC drive method for spinning the motor by getting the information from the FAST algorithm for torque control. The FAST algorithm estimates the motor Flux, Angle, Speed and Torque by using the pre-defined motor parameters and measuring the phase voltages and currents and the total input voltage. The provided information by FAST algorithm is more precise and smooth in the higher speed of the motor because of the higher frequency changes in the motor flux. An incremental rotary encoder improves the system zero speed
performance and precision. To FAST algorithm can be replaced by an incremental encoder provided a position to make torque control more linear and more smooth.

REVISED HISTORY

REVISIION  DESCRIPTION                                    DATE          APPROVAL

A  INITIAL RELEASE                                        MAY 4, 2010    ML

  1. DELETED OUTA, OUTB, OUTC.
  2. ADDED OUTPUT CONNECTOR, TITLED MOTOR.
  3. CONNECTED L2-2, L3-2 AND L4-2 TO MOTOR-1, 2 AND 3, RESPECTIVELY.
  4. DELETED PVDD, GND, +12V AND GND(GND2).
  5. ADDED POWER CONNECTOR, VIN.
  6. CONNECTED VIN-4 TO C1-1.
  7. CONNECTED VIN-2,3 TO GND.
  8. CONNECTED VIN-1 TO +12V.
  9. ADDED TESTPOINTS TO IA-FB, IB-FB, IC-FB AND I-TOTAL.
 10. ADDED 2 PIN HEADERS J2 AND J3 FOR USER POWER ACCESS.
 11. CONNECTED J2-1,2 TO +5V AND GND.
 12. CONNECTED J3-1,2 TO +3.3V AND GND.
 14. ADDED 3 PIN HEADER, JP3, LABELED TACH/SPEED INPUT.
 15. CONNECTED JP3-1,2,3 TO +3.3V, J1-7 AND GND, RESPECTIVELY.
 16. RENAMED S1 TO RSTA.
 17. SWAPPED U1-29 AND U1-30.
 18. ADDED 40 PIN HEADER, J5 AND CONNECTED PINS TO ACTIVE PINS OF J1.
 19. ADDED SWITCHES, S1 AND S2 TO U1-76 AND U1-78.
 20. COPIED DAC1 CIRCUIT, CALLED DAC3, AND CONNECTED TO J1-28.
 21. CHANGED R24-R27 TO 33.0K OHMS.
 22. CHANGED R28-R35, R56-R61 TO 1.00K OHMS.
 23. CHANGED R48, R49, R54 AND R55 TO 49.9K OHMS.
 24. ADDED ISOLATION CIRCUITS.
 25. ADDED 12V CONNECTOR, J9.
 26. CHANGED C4 TO 22UF/100V.
 27. CHANGED C5 AND C6 TO 100V.

B  MARCH 23, 2011    RK

  1. DELETED OUTA, OUTB, OUTC.
  2. ADDED OUTPUT CONNECTOR, TITLED MOTOR.
  3. CONNECTED L2-2, L3-2 AND L4-2 TO MOTOR-1, 2 AND 3, RESPECTIVELY.
  4. DELETED PVDD, GND, +12V AND GND(GND2).
  5. ADDED POWER CONNECTOR, VIN.
  6. CONNECTED VIN-4 TO C1-1.
  7. CONNECTED VIN-2,3 TO GND.
  8. CONNECTED VIN-1 TO +12V.
  9. ADDED TESTPOINTS TO IA-FB, IB-FB, IC-FB AND I-TOTAL.
 10. ADDED 2 PIN HEADERS J2 AND J3 FOR USER POWER ACCESS.
 11. CONNECTED J2-1,2 TO +5V AND GND.
 12. CONNECTED J3-1,2 TO +3.3V AND GND.
 14. ADDED 3 PIN HEADER, JP3, LABELED TACH/SPEED INPUT.
 15. CONNECTED JP3-1,2,3 TO +3.3V, J1-7 AND GND, RESPECTIVELY.
 16. RENAMED S1 TO RSTA.
 17. SWAPPED U1-29 AND U1-30.
 18. ADDED 40 PIN HEADER, J5 AND CONNECTED PINS TO ACTIVE PINS OF J1.
 19. ADDED SWITCHES, S1 AND S2 TO U1-76 AND U1-78.
 20. COPIED DAC1 CIRCUIT, CALLED DAC3, AND CONNECTED TO J1-28.
 21. CHANGED R24-R27 TO 33.0K OHMS.
 22. CHANGED R28-R35, R56-R61 TO 1.00K OHMS.
 23. CHANGED R48, R49, R54 AND R55 TO 49.9K OHMS.
 24. ADDED ISOLATION CIRCUITS.
 25. ADDED 12V CONNECTOR, J9.
 26. CHANGED C4 TO 22UF/100V.
 27. CHANGED C5 AND C6 TO 100V.

The information and materials ("Materials") provided here are provided by Texas Instruments Incorporated ("TI") as a service to its customers and/or suppliers, and may be used for informational purposes only, and only subject to the following terms. By downloading or viewing these Materials, you are signifying your assent to these terms.

1.) These preliminary evaluation schematics are intended for use for PRELIMINARY ENGINEERING DEVELOPMENT AND EVALUATION PURPOSES ONLY and are not considered by Texas Instruments to be fit as a basis for establishing production products or systems. This information may be incomplete in several respects, including but not limited to information relating to required design, marketing, and/or manufacturing-related protective considerations and product safety measures typically found in the end-product incorporating the goods.

2.) Accordingly, neither TI nor its suppliers warrant the accuracy or completeness of the information, text, graphics, links or other items contained within the Materials. TI may make changes to the Materials, or to the products described therein, at any time without notice. TI makes no commitment to update the Materials.

3.) TI assumes no liability for applications assistance, customer product design, software performance, or services that may be described or referenced in the Materials. The user assumes all responsibility and liability for proper and safe design and handling of goods. Accordingly, the user indemnifies TI from all claims arising from its use of the Materials.

4.) TI currently deals with various customers for products, and therefore our arrangement with the user will not be exclusive. TI makes no representations regarding the commercial availability of non-TI components that may be referenced in the Materials.

5.) No license is granted under any patent right or other intellectual property right of TI covering or relating to any combination, machine, or process in which such TI products or services might be or are used. Except as expressly provided herein, TI and its suppliers do not grant any express or implied right to you under any patents, copyrights, trademarks, or trade secret information.

6.) Performance tests and ratings, to the extent referenced in the Materials, are measured using specific computer systems and/or components and reflect the approximate performance of TI products as measured by those tests. Any difference in system hardware or software design or configuration may affect actual performance. Buyers should consult other sources of information to evaluate the performance of systems or components they are considering purchasing.

7.) Resale of TI's products or services with statements different from or beyond the parameters stated by TI for that product or service in official TI data books or data sheets voids all express and any implied warranties for the associated TI product or service, and is an unfair and deceptive business practice, and TI is not responsible for any such use.

8.) The Materials are copyrighted and any unauthorized use may violate copyright, trademark, and other laws. You may only download one copy for your internal use only, unless you are specifically licensed to do otherwise by TI in writing. This is a license, not a transfer of title, and is subject to the following restrictions: You may not:

   (a) modify the Materials (including any associated warranties, conditions, limitations or notices) or use them for any commercial purpose, or any public display, performance, sale or rental;
   (b) decompile, reverse engineer, or disassemble software Materials except and only to the extent permitted by applicable law;
   (c) remove any copyright or other proprietary notices from the Materials;
   (d) transfer the Materials to another person. You agree to prevent any unauthorized copying of the Materials. TI may terminate this license at any time if you are in breach of the terms of this Agreement. Upon termination, you will immediately destroy the Materials.

9.) **EP50S Series**

**Diameter ø50mm Shaft type Absolute Rotary Encoder**

### Features
- Compact size of external diameter ø50mm
- Various output code: BCD, Binary, Gray code
- Various and high resolution(720, 1024 divisions)
- Protection structure IP64(Dust-proof, Oil-proof)

### Applications
- Precision machine tool, Fabric machinery, Robot, Parking system

**Output phase / Output angle**

**Electrical specification**
- PNP open collector output
- Output voltage: Min. (Power supply-1.5)VDC, Load current: Max. 32mA
- Load current: Max. 32mA, Residual voltage: Max. 1VDC
- Response time (Rise/Fall): Min. 800ns, Toff=Max. 800ns (Cable length: 2m, 1 sink = 32mA)
- Max. Response frequency: 35kHz
- Power supply: 5VDC ±5% (Ripple P-P: Max. 5%), 12-24VDC ±5% (Ripple P-P: Max. 5%)
- Current consumption: Max. 100mA (disconnection of the load)
- Insulation resistance: Min. 100MΩ (at 500VDC between all terminals and case)
- Dielectric strength: 750VAC 50/60Hz for 1 minute (Between all terminals and case)
- Connection: Cable type (Cable gland)

- End-play: Max. 0.2mm

※For parallel misalignment, angular misalignment, end-play terms, refer to the F-78 page.
※For flexible coupling (ERB Series) information, refer to the F-71 page.
1 Features

- Available in 8-Bump DSBGA Chip-Sized Package, (See AN-1112, SNVA009)
- Internally Frequency Compensated for Unity Gain
- Large DC Voltage Gain: 100 dB
- Wide Bandwidth (Unity Gain): 1 MHz (Temperature Compensated)
- Wide Power Supply Range:
  - Single Supply: 3V to 32V
  - Or Dual Supplies: ±1.5V to ±16V
- Very Low Supply Current Drain (500 μA)—Essentially Independent of Supply Voltage
- Low Input Offset Voltage: 2 mV
- Input Common-Mode Voltage Range Includes Ground
- Differential Input Voltage Range Equal to the Power Supply Voltage
- Large Output Voltage Swing
- Unique Characteristics:
  - In the Linear Mode the Input Common-Mode Voltage Range Includes Ground and the Output Voltage Can Also Swing to Ground, even though Operated from Only a Single Power Supply Voltage.
  - The Unity Gain Cross Frequency is Temperature Compensated.
  - The Input Bias Current is also Temperature Compensated.
- Advantages:
  - Two Internally Compensated Op Amps
  - Eliminates Need for Dual Supplies
  - Allows Direct Sensing Near GND and \( V_{\text{OUT}} \) Also Goes to GND
  - Compatible with All Forms of Logic
  - Power Drain Suitable for Battery Operation

2 Applications

- Active Filters
- General Signal Conditioning and Amplification
- 4- to 20-mA Current Loop Transmitters

3 Description

The LM158 series consists of two independent, high gain, internally frequency compensated operational amplifiers which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage.

Application areas include transducer amplifiers, dc gain blocks and all the conventional op-amp circuits which now can be more easily implemented in single power supply systems. For example, the LM158 series can be directly operated off of the standard 3.3-V power supply voltage which is used in digital systems and will easily provide the required interface electronics without requiring the additional ±15V power supplies.

The LM358 and LM2904 are available in a chip sized package (8-Bump DSBGA) using TI’s DSBGA package technology.

(1) Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Recommended Operating Conditions indicate conditions for which the device is intended to be functional, but specific performance is not ensured. For ensured specifications and the test conditions, see the Electrical Characteristics.

(2) Refer to RETS158AX for LM158A military specifications and to RETS156X for LM158 military specifications.

(3) If Military/Aerospace specified devices are required, please contact the TI Sales Office/Distributors for availability and specifications.

(4) For operating at high temperatures, the LM358/LM358A, LM2904 must be derated based on a 125°C maximum junction temperature and a thermal resistance of 120°C/W for PDIP, 182°C/W for TO-99, 189°C/W for SOIC package, and 230°C/W for DSBGA, which applies for the device soldered in a printed circuit board, operating in a still air ambient. The LM258/LM258A and LM158/LM158A can be derated based on a +150°C maximum junction temperature. The dissipation is the total of both amplifiers—use external resistors, where possible, to allow the amplifier to saturate or to reduce the power which is dissipated in the integrated circuit.

(5) Short circuits from the output to V* can cause excessive heating and eventual destruction. When considering short circuits to ground, the maximum output current is approximately 40 mA independent of the magnitude of V*. At values of supply voltage in excess of +15 V, continuous short-circuits can exceed the power dissipation ratings and cause eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.

(6) This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the op amps to go to the V* voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than −0.3 V (at 25°C).

<td>65</td>
<td>100</td>
</tr>
</tbody>
</table>

(1) These specifications are limited to −55°C ≤ T<sub>A</sub> ≤ +125°C for the LM158/LM158A. With the LM258/LM258A, all temperature specifications are limited to −25°C ≤ T<sub>A</sub> ≤ 85°C, the LM358/LM358A temperature specifications are limited to 0°C ≤ T<sub>A</sub> ≤ 70°C, and the LM2904 specifications are limited to −40°C ≤ T<sub>A</sub> ≤ 85°C.

(2) V<sub>O</sub> = 1.4 V, R<sub>S</sub> = 0 Ω with V<sup>*</sup> from 5 V to 30 V; and over the full input common-mode range (0 V to V<sup>*</sup>−1.5 V) at 25°C. For LM2904, V<sup>*</sup> from 5 V to 26 V.

(3) The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.

(4) The input common-mode voltage of either input signal voltage should not be allowed to go negative by more than 0.3 V (at 25°C). The upper end of the common-mode voltage range is V<sup>*</sup>−1.5 V (at 25°C), but either or both inputs can go to 32 V without damage (26 V for LM2904), independent of the magnitude of V<sup>*</sup>.

---

(5) Due to proximity of external components, insure that coupling is not originating via stray capacitance between these external parts. This typically can be detected as this type of capacitance increases at higher frequencies.

(6) Short circuits from the output to \( V^+ \) can cause excessive heating and eventual destruction. When considering short circuits to ground, the maximum output current is approximately 40 mA independent of the magnitude of \( V^+ \). At values of supply voltage in excess of \( +15 \, \text{V} \), continuous short-circuits can exceed the power dissipation ratings and cause eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.

|                              | Sink   | \(V_{IN} = 1\ V\), \(V_{IN} = 0\ V\), \(V^+ = 15\ V\), \(V_0 = 2\ V\), \(V_{IN} = 1\ V\), \(V^+ = 0\ V\), \(T_a = 25^\circ C\), \(V_{CM} = 200\ mV\), \(V^+ = 15\ V\) | 10    | 20      | 10     | 20      | mA   |
| Short Circuit to Ground       | \(T_a = 25^\circ C\), See\(^{(6)}\), \(V^+ = 15\ V\) | 40    | 60      | 40     | 60      | mA   |
| Input Offset Voltage          | See\(^{(2)}\) | 9     | 10      | 9      | 10      | mV   |
| Input Offset Voltage Drift    | \(R_E = 0\ \Omega\) | 7     | 7       | 7      | \muV/V | C     |
| Input Offset Current          | \(I_{IN(+) - I_{IN(-)}}\) | 150   | 45      | 200    | nA     |
| Input Offset Current Drift    | \(R_E = 0\ \Omega\) | 10    | 10      | 10     | \muA/V | C     |
| Input Bias Current            | \(I_{IN(+) or I_{IN(-)}}\) | 40    | 500     | 40     | 500     | nA   |

\(^{(1)}\) These specifications are limited to \(-55^\circ C \leq T_a \leq +125^\circ C\) for the LM158/LM158A. With the LM258/LM258A, all temperature specifications are limited to \(-25^\circ C \leq T_a \leq +85^\circ C\), the LM358/LM358A temperature specifications are limited to \(0^\circ C \leq T_a \leq 70^\circ C\), and the LM2904 specifications are limited to \(-40^\circ C \leq T_a \leq +85^\circ C\).

\(^{(2)}\) \(V_0 = 1.4\ V\), \(R_E = 0\ \Omega\) with \(V^+\) from \(5\ V\) to \(30\ V\), and over the full input common-mode range \((0\ V \leq V^+ \leq 1.5\ V)\) at \(25^\circ C\). For LM2904, \(V^+\) from \(5\ V\) to \(26\ V\).

\(^{(3)}\) The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.

\(^{(4)}\) The input common-mode voltage of either input signal voltage should not be allowed to go negative by more than 0.3 V (at \(25^\circ C\)). The upper end of the common-mode voltage range is \(V^+\)-1.5 V (at \(25^\circ C\)), but either or both inputs can go to 32 V without damage (26 V for LM2904), independent of the magnitude of \(V^+\).

\(^{(5)}\) Due to proximity of external components, ensure that coupling is not originating via stray capacitance between these external parts. This typically can be detected as this type of capacitance increases at higher frequencies.

\(^{(6)}\) Short circuits from the output to \(V^+\) can cause excessive heating and eventual destruction. When considering short circuits to ground, the maximum output current is approximately 40 mA independent of the magnitude of \(V^+\). At values of supply voltage in excess of +15 V, continuous short-circuits can exceed the power dissipation ratings and cause eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.

Simple by design, the S2 is an all-in-one pneumatic positioning system capable of tackling high speed and high force applications while linearly positioning a cylinder anywhere along its stroke.

**Features**
- Easy Tuning
- Simple Setup and Wiring
- Wide Range of Input Pressures
- Minimized Air Consumption
- All-in-One Package

**Applications**
- Line and Hopper Feed Rate
- Edge Guide Positioning
- Case Erect and Pack
- Pick and Place
- Lane Divide and Divert
- Gripper Position Control
- Quality Control Sorting
- Component Placing
- Actuate and Pilot Process Valves
- Material Processing
- Level and Elevator Control
- Sluice Gate Control
- Rotary Indexing and Positioning

**Compatibility**
Add position control to almost any application.
Typical compatibility:
- Double Acting
- Non-Repairable Cylinders
- ISO & Tie Rod Cylinders
- Grippers & End Effectors
- Vane or Rack & Pinion
- Rotary Cylinders

**Mechanical Specifications**
- **Pressure:**
  - 0...10 bar (0...150 psig)
- **Ports:**
  - 1/4” NPTF
- **Connector:**
  - 5-pin M8 x 1 (male)
- **Mounting:**
  - 2 x M5 (10-32) Thru Holes
- **Temperature Range:**
  - 0°C – 40°C (32°F – 104°F)
- **Filtration:**
  - 5 µm Particulate
  - 0.3 µm Coalescing
- **Media:**
  - Unlubricated, Dry, Neutral Gas
- **Height:**
  - 126 mm (5.00 in)
- **Width:**
  - 64 mm (2.50 in)
- **Length:**
  - 68 mm (2.75 in)
- **Weight:**
  - 0.91 kg (2.00 lbs)

**Material Specifications**
- **Body:**
  - Aluminum 6061
- **Caps:**
  - PA66 30% Glass Filled Nylon
- **Other:**
  - Nitrile, 440C SS, Nickel Plated Steel

**Electrical Specifications**
- **Power Requirement:**
  - 12 ± 2 VDC
  - 24 ± 4 VDC @ 20W
- **Command Input Impedance:**
  - 0...10VDC: 100kΩ
  - 4...20mA: 210Ω
- **Feedback Input Impedance:**
  - 0...10VDC: 100kΩ
  - 4...20mA: 210Ω
- **Command Input:**
  - Configurable 0...10 VDC; 4...20mA
- **Feedback Input:**
  - Configurable 0...10 VDC; 4...20mA
- **Electronic Adjustments:**
  - USB-Connectable User Interface
- **Status Indications:**
  - 2 Power and Status LEDs
- **Excitation:**
  - +10V (15mA max)

**Performance Specifications**
- **Positional Accuracy:**
  - ± 0.1...1% of Full Scale (typical)
- **Flow:**
  - 1300 SLPM 5.5 → 0 bar
  - (46 SCFM 80 → 0 psi)
- **Leak Rate:**
  - 5.7 SLPM 10 → 0 bar
  - (12 SCFH 150 → 0 psi)
- **Order Code:**
  - S2-025-U-04
The S2 Servo Pneumatic Proportional Control System is ideal for applications requiring high speed and high forces simultaneously. Speeds up to 2.0 m/sec are achievable while slowing the cylinder to a smooth controlled stop, preventing premature cylinder wear and damage. Handling 50+ kilogram masses, it is capable of 0.5 m/sec across a selection of cylinders. The ability to handle heavy loads while quickly and accurately following a changing input signal makes the S2 the ideal choice for machine designers.

**Maximum Cylinder Speed vs Moving Mass: Bore Size Comparison**

Note: Based on test results from typical setup: 250mm stroke guided horizontal cylinder with 5.5 bar inlet pressure. Changes in moving mass, cylinder orientation or other system parameters will impact maximum speed. Figures are to be used for general guidance only.

1 TMS320F2806xF InstaSPIN™-FOC Enabled MCUs

TMS320F2806xF are the first family of devices (69F, 68F, and 62F — 80- or 100-pin packages) from Texas Instruments that include the FAST™ (Figure 1) estimator and additional motor control functions needed for cascaded speed and torque loops for efficient three-phase field-oriented motor control (FOC).

Together — with F2806xF peripheral drivers in user code — they enable a sensorless (also known as self-sensing) InstaSPIN-FOC solution which can identify, tune the torque controller and efficiently control your motor in minutes, without the use of any mechanical rotor sensors. This entire package is called InstaSPIN-FOC, which is made available in ROM. The user also has the option of executing all FOC functions in user memory (FLASH or RAM), which makes calls to the proprietary FAST estimator firmware in ROM. InstaSPIN-FOC was designed for flexibility to accommodate a range of system software architectures and customization. The range of this flexibility is shown in Figure 2 and Figure 3.

This document is a supplement to all standard TMS320F2806x documentation, including the standard device data sheet [TMS320F2806x Piccolo Microcontrollers (literature number SPRS698)], technical reference manual, and user’s guides. An additional document included with the InstaSPIN-FOC documentation package is the TMS320F2806xF, TMS320F2802xF InstaSPIN-FOC/TMS320F2806xM InstaSPIN-MOTION User’s Guide (literature number SPRUHJ1), which covers the scope and functionality of:

- F2806xF devices
- F2806xF ROM contents
- FAST flux estimator
- InstaSPIN-FOC system solutions.
Figure 1. FAST - Estimating Flux, Angle, Speed, Torque - Automatic Motor Identification
2 FAST Estimator Features

- Unified observer structure which exploits the similarities between all motors that use magnetic flux for energy transduction
  - Both synchronous (BLDC, SPM, IPM), and asynchronous (ACIM) control are possible
  - Salient compensation for Interior Permanent Magnet motors: observer tracks rotor flux and angle correctly when \( L_s-d \) and \( L_s-q \) are provided
- Unique, high quality motor feedback signals for use in control systems
  - High-quality flux signal for stable flux monitoring and field weakening
  - Superior rotor flux angle estimation accuracy over wider speed range compared to traditional observer techniques independent of all rotor parameters for ACIM
  - Real-time low-noise motor shaft speed signal
  - Accurate high bandwidth torque signal for load monitoring and imbalance detection
- Angle estimator converges within first cycle of the applied waveform, regardless of speed
- Stable operation in all power quadrants, including generator quadrants
- Accurate angle estimation at steady state speeds below 1 Hz (typ) with full torque
- Angle integrity maintained even during slow speed reversals through zero speed
- Angle integrity maintained during stall conditions, enabling smooth stall recovery
- Motor Identification measures required electrical motor parameters of unloaded motor in under 2 minutes (typ)
  - “On-the-fly” stator resistance recalibration (online \( R_s \)) tracks stator resistance changes in real time, resulting in robust operation over temperature. This feature can also be used as a temperature sensor of the motor’s windings (basepoint calibration required)
  - Superior transient response of rotor flux angle tracking compared to traditional observers
  - PowerWarp™ adaptively reduces current consumption to minimize the combined (rotor and stator) copper losses to the lowest, without compromising ACIM output power levels

3 InstaSPIN™-FOC Solution Features

- Includes the Flux Angle Speed Torque (FAST) estimator, used to measure rotor flux (both magnitude and angle) in a sensorless field-oriented control (FOC) system
- Automatic torque (currentless) loop tuning, with option for user adjustments
- Automatic speed loop tuning provides stable operation for most applications. (Better transient response can be obtained by optimizing parameters for a particular application)
- Automatic or manual field weakening and field boosting
- Bus Voltage compensation
- Automatic offset calibration insures quality samples of feedback signals
4 InstaSPIN-FOC Block Diagrams

</tbody>
</table>
FAST Provides Sensorless FOC Performance

6 FAST Provides Sensorless FOC Performance

6.1 FAST Estimator Replaces Mechanical Sensor

Field-oriented control (FOC) of an electric motor results in superior torque control, lower torque ripple, and in many cases, improved efficiency compared to traditional AC control techniques. For best dynamic response, rotor flux referenced control algorithms are preferred to stator flux referenced techniques. To function correctly, these systems need to know the spatial angle of the rotor flux with respect to a fixed point on the stator frame (typically the magnetic axis of the phase A stator coil). This has traditionally been accomplished by a mechanical sensor (for example, encoder or resolver) mounted to the shaft of the motor. These sensors provide excellent angle feedback, but inflict a heavy toll on the system design. There are six major system impacts resulting from sensored angle feedback, as discussed below and illustrated in Figure 4:

1. The sensor itself is very expensive (often over $2500 for a good resolver and several dollars for high volume integrated encoders).
2. The installation of the sensor requires skilled assembly, which increases labor costs.
3. The sensor often requires separate power supplies, which increases system costs and reduces reliability.
4. The sensor is the most delicate component of the system, which impacts system reliability, especially in harsh real-world applications.
5. The sensor feedback signals are brought back to the controller board via connectors, which also increases system costs and can significantly reduce reliability, depending on the type of connector.
6. The cabling required to bring the sensor signals back to the controller creates multiple challenges for the system designer:
   • Additional costs for the cable, especially if there is a substantial distance between the motor and controller.
   • Susceptibility to sources of noise, which requires adding expense to the cable with special shielding or twisted pairs.
   • The sensor and associated cabling must be earth grounded for safety reasons. This often adds additional cost to isolate these signals, especially if the processor which processes the sensor signals is not earth grounded.

In some applications where the motor is enclosed (for example, compressors), a sensored solution is impractical due to the cost of getting the feedback wires through the casing. For these reasons, designers of FOC systems are highly motivated to eliminate the sensor altogether, and obtain the rotor flux angle information by processing signals which are already available on the controller circuit board. For synchronous machines, most techniques involve executing software models of the motor being controlled to estimate the back-EMF waveforms (rotor flux), and then processing these sensed waveforms to extract an estimation of the rotor shaft angle, and a derivation of its speed. For asynchronous machines the process is a bit more complicated, as this software model (observer) must also account for the slip which exists between the rotor and rotor flux.

However, in both cases, performance suffers at lower speeds due to the amplitude of the back-EMF waveforms being directly proportional to the speed of the motor (assuming no flux weakening). As the back-EMF amplitude sinks into the noise floor, or if the ADC resolution cannot faithfully reproduce the small back-EMF signal, the angle estimation falls apart, and the motor drive performance suffers.

To solve the low-speed challenge, techniques have been created that rely on high frequency injection to measure the magnetic irregularities as a function of angle (that is, magnetic saliency) to allow accurate angle reconstruction down to zero speed. However, this introduces another set of control problems. First, the saliency signal is non-existent for asynchronous motors and very small for most synchronous machines (especially those with surface mount rotor magnets). For the motors that do exhibit a strong saliency signal (for example, IPM motors), the signal often shifts with respect to the rotor angle as a function of loading, which must be compensated. Finally, this angle measurement technique only works at lower speeds where the fundamental motor frequency does not interfere with the interrogation frequency. The control system has to create a mixed-control strategy, using high-frequency injection tracking at low speed, then move into Back-EMF based observers at nominal and high speeds.
With any technique, the process of producing a stable software sensor is also extremely challenging, as this motor model (observer) is essentially its own control system that needs to be tuned per motor across the range of use. This tuning must be done with a stable forward control loop. Needed is a stable torque (and usually speed) loop to tune the observer, but how do you pre-tune your forward control without a functioning observer? One option is to use a mechanical sensor for feedback to create stable current and speed loops, and then tune your software sensor in parallel to the mechanical sensor. However, the use of a mechanical sensor is often not practical. This problem has delayed market use of software sensors for sensorless FOC control.

Figure 4. Sensored FOC System

In summary, these existing solutions all suffer from various maladies including:

- Poor low-speed performance (back-EMF and SMO)
- Poor high-speed performance (saliency observers)
- Poor dynamic response
- Calculation intensive (multi-modal observers)
- Parameter sensitivity
- Requirement for observer tuning.

The most recent innovation in the evolution of sensorless control is InstaSPIN-FOC. Available as a C-callable library embedded in on-chip ROM on several TI processors, InstaSPIN-FOC was created to solve all of these challenges, and more. It reduces system cost and development time, while improving performance of three-phase variable speed motor systems. This is achieved primarily through the replacement of mechanical sensors with the proprietary FAST estimator. FAST is an estimator that:

- Works efficiently with all three phase motors, taking into account the differences between synchronous/asynchronous, salient/non-salient, and permanent/non-permanent/induced magnets.
- Dramatically improves performance and stability across the entire operating frequency and load range for a variety of applications.
- Removes the manual tuning challenge of traditional FOC systems:
  - Qbservers and estimators, completely removes required tuning.
  - Current loop regulators, dramatically reduces required tuning.
FAST Provides Sensorless FOC Performance

- Eliminates or reduces motor parameter variation effects.
- Automatically designs a stable and functional control system for most motors in under two minutes.

6.2 **Rotor Angle Accuracy Critical for Performance**

Why has the need for a precise estimation of the rotor flux angle driven many to use mechanical sensors?

For efficient control of three-phase motors, the objective is to create a rotating flux vector on the stator aligned to an ideal orientation with respect to the rotor in such a way that the rotor field follows the stator field while creating necessary torque and using the minimum amount of current.

- **Stator**: stationary portion of the motor connected to the microprocessor-controlled inverter.
- **Ideal Orientation**: 90 degrees for non-salient synchronous; slightly more for salient machines, and slightly less in asynchronous machines since part of the current vector is also used to produce rotor flux.
- **Rotor**: rotating portion of the motor, produces torque on the shaft to do work.

To achieve this, you need to extract the following information from the motor:

- Current being consumed by each phase.
- Precise relative angle of the rotor flux magnetic field (usually within ±3 electrical degrees), so you can orient your stator field correctly.
- For speed loops, you also need to know rotor speed.

6.3 **Phase Currents Key to Estimator Accuracy**

Resistor shunt current measurement is a very reasonable technique for measuring phase current in a motor control inverter. There are three widely used examples, the 1-, 2-, and 3-shunt resistor measurements. While at first the 1- and 2-shunt techniques seem to reduce cost, they require much faster and more expensive amplifier circuits. These 1- and 2-shunt current measurements also limit the capability of the current feedback which will limit the ability of the drive to use the full voltage that is provided to the inverter. The 3-shunt technique is superior and not much different in cost due to the advantage of using cheap slow current amplifier circuits. For best performance and cost with the FAST and InstaSPIN-FOC, the 3-shunt technique is recommended.

For more details, see the TMS320F2806xF, TMS320F2802xF InstaSPIN-FOC/TMS320F2806xM InstaSPIN-MOTION User's Guide (literature number SPRUHJ1).
7 Evaluating FAST and InstaSPIN-FOC Performance

FAST and InstaSPIN-FOC performance data is being collected and will be provided in a future revision of this document.

8 Microcontroller Resources

The F2806xF microcontroller resources required by the InstaSPIN libraries are discussed in detail in the TMS320F2806xF, TMS320F2802xF InstaSPIN-FOC/TMS320F2806xM InstaSPIN-MOTION User’s Guide (literature number SPRUHJ1).

Specifically for the library implementation and where the code is loaded and executed from, the following resources categories are discussed in this document:

- CPU Utilization
- Memory Allocation
- Stack Utilization
- Digital and Analog Pins Utilization
InstaSPIN-FOC provides flexibility throughout its design, including its software execution clock tree. Figure 6 illustrates the options available to the designer to manage the real-time scheduling of each of the major software functions. Balancing motor performance with CPU loading is not difficult, shortening system integration time.

Figure 6. Software Execution Clock Tree Provides Flexibility with Real-Time Scheduling

Executing from single-cycle memory, total execution time for the full implementation of InstaSPIN-FOC will depend on the software execution clock tree. Table 2 shows the CPU cycles used when a full implementation of InstaSPIN is done, as well as users’ code is loaded to FLASH. Note the impact of the software execution tree to total execution time. Table 3 shows the CPU loading and available MIPS for other system functions. The execution time does not change significantly from FULL to MIN implementations since the FAST block requires the largest number of CPU cycles and is in ROM for all implementations.

8.2 Pin Utilization

Flexibility in the design of InstaSPIN-FOC allows for multiple motors to be supported. Table 7 lists the minimum and maximum pins used per motor. Note that a F2806xF microcontroller provides (14) ePWM outputs with the 100-pin package, and (12) with the 80-pin.

Appendix A Definition of Terms and Acronyms

ACIM — Alternating current induction motor.

CCStudio — Code Composer Studio.

FAST — Unified observer structure which exploits the similarities between all motors that use magnetic flux for energy transduction, automatically identifying required motor parameters and providing the following motor feedback signals:
  • High-quality Flux signal for stable flux monitoring and field weakening.
  • Superior rotor flux Angle estimation accuracy over wider speed range compared to traditional observer techniques independent of all rotor parameters for ACIM.
  • Real-time low-noise motor shaft Speed signal.
  • Accurate high bandwidth Torque signal for load monitoring and imbalance detection.

FOC — Field-oriented control.

Forced-Angle — Used for 100% torque at start-up until the FAST rotor flux angle tracker converges within first electrical cycle.

InstaSPIN-FOC — Complete sensorless FOC solution provided by TI on-chip in ROM on select devices (FAST observer, FOC, speed and current loops), efficiently controlling your motor without the use of any mechanical rotor sensors.

IPM — Interior permanent magnet motor.

Motor Parameters ID or Motor Identification — A feature added to InstaSPIN-FOC, providing a tool to the user so that there is no barrier between running a motor to its highest performance even though the motor parameters are unknown.

PI — Proportional-integral regulator.

PMSM — Permanent magnet synchronous motor.

PowerWarp™ — Mode of operation used for AC induction motors (ACIM) that allows minimum current consumption.

Rs-Offline Recalibration — InstaSPIN-FOC feature that is used to recalibrate the stator resistance, Rs, when the motor is not running.

Rs-Online Recalibration — InstaSPIN-FOC feature that is used to recalibrate the stator resistance, Rs, while the motor is running in closed loop.

SVM — Space-vector modulation.
# Revision History

Changes from Original (February 2013) to A Revision | Page
--- | ---
- Changed second paragraph in Section 1 | 4
- Deleted Table 2, Hardware Features from Section 8 | 13
- Deleted Figure 6, Functional Block Diagram from Section 8 | 13
- Deleted Figure 7, Peripheral Blocks from Section 8 | 13

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.
Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have not been so designated is solely at the Buyer’s risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
